

**SOS IN COMPUTER SCIENCE & APPLICATION  
JIWAJI UNIVERSITY**

**Class : MBA (E-Commerce) II Semester**

**Subject : OOPS using C++**

**Paper Code: (201)**

**Topic: Friend Function In C++**

# Introduction To Friend Function

- ▶ In some real-time applications, sometimes we might want to access data outside the bundled unit. For example, an outsider class might want to access private and protected data of a C++ class. C++ provides a facility for accessing private and protected data by means of a special feature called “friend” function or class which we will discuss here in this tutorial.
- ▶ A friend function in C++ is a function that is preceded by the keyword “friend”. When the function is declared as a friend, then it can access the private and protected data members of the class.

# Declaration of friend function in C++

- ▶ **class** class\_name
- ▶ {
- ▶ **friend** data\_type function\_name(argument/s);  
// syntax of friend function.
- ▶ };
- ▶ In the above declaration, the friend function is preceded by the keyword **friend**. The function can be defined anywhere in the program like a normal C++ function. The function definition does not use either the keyword **friend** or **scope resolution operator**.

# Characteristics of a Friend function:

- ▶ The function is not in the scope of the class to which it has been declared as a friend.
- ▶ It cannot be called using the object as it is not in the scope of that class.
- ▶ It can be invoked like a normal function without using the object.
- ▶ It cannot access the member names directly and has to use an object name and dot membership operator with the member name.
- ▶ It can be declared either in the private or the public part.
- ▶ Friend function has to be declared in all classes whose private or protected members needs to be accessed but all the classes will share the same definition.

# Program using Friend Function

```
▶ #include <iostream>
▶ using namespace std;
▶ class B;      // forward declarartion.
▶ class A
▶ {
▶     int x;
▶     public:
▶     void setdata(int i)
▶     {
▶         x=i;
▶     }
▶     friend void min(A,B);    // friend function.
▶ };
▶ class B
▶ {
▶     int y;
▶     public:
▶     void setdata(int i)
▶     {
▶         y=i;
▶     }
▶     friend void min(A,B);    // friend function
▶ };
```

# Program(cont.)–

```
▶ . void min(A a, B b)
▶ {
▶     if(a.x<=b.y)
▶         std::cout << a.x << std::endl;
▶     else
▶         std::cout << b.y << std::endl;
▶ }
▶ int main()
▶ {
▶     A a;
▶     B b;
▶     a.setdata(10);
▶     b.setdata(20);
▶     min(a,b);
▶     return 0;
▶ }
▶ Output:
▶ 10
```

# Explanation & Friend Class

- ▶ In the above example, min() function is friendly to two classes, i.e., the min() function can access the private members of both the classes A and B.
- ▶ **C++ Friend class**
- ▶ A friend class can access both private and protected members of the class in which it has been declared as friend.
- ▶ **Let's see a simple example of a friend class.**

# Program using Friend Class

```
▶ #include <iostream>
▶
▶ using namespace std;
▶
▶ class A
▶ {
▶     int x =5;
▶     friend class B;        // friend class.
▶ };
▶ class B
▶ {
▶     public:
▶     void display(A &a)
▶     {
▶         cout<<"value of x is : "<<a.x;
▶     }
▶ };
▶ .
```

# Cont.

- ▶ **int** main()
- ▶ {
- ▶   A a;
- ▶   B b;
- ▶   b.display(a);
- ▶   **return** 0;
- ▶ }
- ▶ **Output:**
- ▶ value of x is : 5

# Explanation Of code

- ▶ In the example given in previous slide, class B is declared as a friend inside the class A. Therefore, B is a friend of class A. Class B can access the private members of class A.
